### Introduction to Bloom Filter

### ■ What's it?

 $\Box$  A bit vector that compactly represents a set of items (keys)

- $\blacksquare$  Support key query/insert operations
- Tell definitely if a key is NOT present; couldn't tell with guarantee that a key is indeed present (a few false positives may exist)
- Where is Bloom Filter (BF) used for?
	- □ Database applications
	- $\Box$  Network applications
		- E.g., router
	- $\square$  Backup applications
		- E.g., chunking based data dedupe (not found $\rightarrow$ new chunk!)

## Extending BF to Secondary Storage Device

### ■ Why?

- $\square$  In-RAM BF size is limited by the available RAM size on the machine. However, some Apps like dedupe needs BF size beyond RAM capacity.
- Main concept
	- $\Box$  Utilize a limited amount of RAM space combined with a much larger secondary storage space to form a BF
- **Secondary storage device choices** 
	- $\Box$  flash memory vs. magnetic disk

### Building a BF with Flash Memory

 $\mathbb{R}^3$ Pros

 $\Box$  It requires only 1 flash page R /key query  $\rightarrow$  best for key query

- $\mathcal{L}^{\mathcal{L}}$  Cons
	- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
	- $\Box$  Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally pre-partitioned
- $\Box$  BF size has to be determined in advance and could not be **MSST 2011 Changed during the run**

 $\mathbb{R}^3$ Pros

 $\Box$  It requires only 1 flash page R /key query  $\rightarrow$  best for key query

- $\mathcal{L}^{\mathcal{L}}$  Cons
	- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
	- $\Box$  Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally pre-partitioned
- $\Box$  BF size has to be determined in advance and could not be **MSST 2011 Changed during the run**

 $\Box$  It requires only 1 flash page R /key query  $\rightarrow$  best for key query

#### $\mathcal{L}^{\mathcal{L}}$ Cons

- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
- $\Box$  Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally pre-partitioned
- $\Box$  BF size has to be determined in advance and could not be **MSST 2011 Changed during the run**

### update sub-BF

#### $\mathcal{L}_{\mathcal{A}}$ Single-layer Design

RAM write buffer

#### $\mathbb{R}^3$ Pros

 $\Box$  It requires only 1 flash page R /key query  $\rightarrow$  best for key query

#### $\mathcal{L}^{\mathcal{L}}$ Cons

- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
- П. Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally pre-partitioned
- $\Box$  BF size has to be determined in advance and could not be **MSST 2011 Changed during the run**

### update sub-BF

 $\mathcal{L}^{\mathcal{L}}$ Single-layer Design

RAM write buffer

Write sub-BF back<br>Applied updates

- $\square$  1 flash page R /key query  $\rightarrow$  best for key query
- $\mathcal{L}^{\mathcal{L}}$ Cons

Pros

 $\mathbb{R}^3$ 

- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
- $\Box$  Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally pre-partitioned
- $\Box$  BF size has to be determined in advance and could not be **MSST 2011 Changed during the run**

**Linear-chaining Design** 

#### $\mathcal{L}^{\text{max}}$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}^{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

**Linear-chaining Design** 

#### $\mathcal{L}_{\mathcal{A}}$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}^{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

**Linear-chaining Design** 

**BF 1** insert more keys ...

#### $\mathcal{L}^{\text{max}}$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}_{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

### **Linear-chaining Design**

#### $\mathcal{L}^{\text{max}}$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}_{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

**Linear-chaining Design** 

#### $\mathcal{L}^{\text{max}}$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}^{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

**Linear-chaining Design** 

#### $\blacksquare$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized
- $\Box$  BF size grows dynamically as the # of chained BFs increased
- $\mathcal{L}_{\text{max}}$  Cons
	- $\Box$ Querying a key may require traverse all chained BFs
	- $\Box$  False positive errors tend to be much higher than single-layer design

**Linear-chaining Design** 

#### $\blacksquare$ Pros

- $\Box$  best for key insertion: each chained BF will be only written once, hence the flash write # is minimized

### Proposed Forest-structured BF(FBF) Design

 $\mathcal{L}_{\mathcal{A}}$  Goal: To strike a balance between key query and insert performance

## Proposed Buffer Space Management Scheme for FBF Design

- $\mathcal{L}_{\mathcal{A}}$  FBF inserts new keys into the lowest-layer of the forest only, which optimizes for
	- $\Box$  $\Box$  allowing larger buffer space per sub-BF
	- $\Box$ Minimize the target address range for flash writes
- FBF manages buffer space by
	- $\Box$ grouping consecutive sub-BFs into blocks
	- $\Box$ buffering key insertions per block in a in-RAM set data structure
	- $\Box$  keeping all sets into a linked-list
	- $\square$  selecting the block corresponding to the set containing most insertions to update when the entire buffer space is used up.

### Experimental Evaluation Results

### ■ Workload description:

- $\Box$  A sequence (20 millions) of SHA1 hash value of 160-bit length. Each of which represents a chunk-id produced by standard content-defined chunking algorithm; 57% are unique chunk-ids
- □ BF access pattern: Key query & insert are interleaved
- $\mathcal{L}^{\text{max}}$ ■ TR vs. buffer size for both cache managing schemes:

### Experimental Evaluation Results

 Throughput Rate (TR) vs. buffer sizes for forest-structure BF and single-layer BF

### Summary of Contributions

- We present a novel BF design (FBF) with flash memory that
	- $\square$  strikes a balance between key query and key insert performance
	- $\Box$  $\Box$  achieves a significantly higher TR with the same buffer size compared with existing designs.
- **Furthermore, our proposed buffer space managing scheme** reduces the number of flash writes remarkably (e.g., 50% less), even with the same existing BF design.

## Thank you!

## Thank you!

 $\Box$  requires only 1 flash page R /key query  $\rightarrow$  best for key query

#### $\mathcal{L}^{\mathcal{L}}$ Cons

- $\Box$ Buffer space is very limited for each sub-BF $\rightarrow$  many flash readthen-write ops are required for each sub-BF during the run.
- $\Box$  Some sub-BFs tend to receive more keys than others (by single hash function), but buffer space is equally partitioned ahead
- $\Box$  BF size should be determined in advance and could not be **MSST 2011 Changed during the run**
